SI231 - Matrix Computations, Fall 2020-21

Homework Set #5

Prof. Yue Qiu and Prof. Ziping Zhao

Name: LiuChang Major: Master in IE

Student No.: 2020232161 E-mail: liuchang3@shanghaitech.edu.cn

Acknowledgements:

1) Deadline: 2020-12-07 23:59:00

2) Submit your homework at **Gradescope**. Homework #5 contains two parts, the theoretical part the and the programming part.

- 3) About the theoretical part:
 - (a) Submit your homework in **Homework 5** in gradescope. Make sure that you have correctly select pages for each problem. If not, you probably will get 0 point.
 - (b) Your homework should be uploaded in the **PDF** format, and the naming format of the file is not specified.
 - (c) No handwritten homework is accepted. You need to use LATEX in principle.
 - (d) Use the given template and give your solution in English. Solution in Chinese is not allowed.
- 4) About the programming part:
 - (a) Submit your codes in Homework 5 Programming part in gradescope.
 - (b) When handing in your homework in gradescope, package all your codes into your_student_id+hw4_code.zip and upload. In the package, you also need to include a file named README.txt/md to clearly identify the function of each file. (".zip" format package rather than ".rar, .7zip" should be uploaded, solution of the results should be named according to requirements.)
 - (c) Make sure that your codes can run and are consistent with your solutions.
- 5) Late Policy details can be found in the bulletin board of Blackboard.

STUDY GUIDE

This homework concerns the following topics:

- Regularization, see Lecture 8 of Zhao, Lecture 20 of Qiu.
- SVD computation, see Lecture 7 of Zhao, Lecture 18 of Qiu.
- Iterative methods, see Lecture 2 of Zhao, Lecture 21 of Qiu.
- Application of SVD, PCA, see Lecture 7 of Zhao, Lecture 19 of Qiu.

I. LEAST SQUARE WITH REGULARIZATION

Problem 1. In this problem, we will learn how to solve LS when there is noise. for some $\lambda > 0$, where the term $\lambda ||\mathbf{x}||_k^k$ is added to improve the system conditioning, thereby attempting to reduce noise sensitivity. Usually, we set k = 1 which is called $\ell 1$ regularization, or set k = 2 which is called $\ell 2$ regularization.

ℓ1 regularized LS:

$$\mathbf{x_{LS}} = \min_{\mathbf{X} \in \mathbb{R}^n} f(\mathbf{x}), \quad f(\mathbf{x}) = ||\mathbf{A}\mathbf{x} - \mathbf{y}||_2^2 + \lambda ||\mathbf{x}||_1$$
 (1)

ℓ2 regularized LS:

$$\mathbf{x_{LS}} = \min_{\mathbf{X} \in \mathbb{R}^n} f(\mathbf{x}), \quad f(\mathbf{x}) = ||\mathbf{A}\mathbf{x} - \mathbf{y}||_2^2 + \lambda ||\mathbf{x}||_2^2$$
 (2)

Write programs to solve the regularized least square problem, any programming language is suitable. where $\mathbf{A} \in \mathbb{R}^{m \times n}$ is a matrix representing the predefined data set with m data samples of n dimensions (m=1000, n=210), and $\mathbf{y} \in \mathbb{R}^m$ represents the labels. The data samples are provided in the "data.txt" file, and the labels are provided in the "label.txt" file, you are supposed to load the data before solving the problem. In this problem, we set $\lambda = 0.1$ for two algorithms.

1) (8 points) Solve $\ell 1$ regularized LS using Majorization-Minimization method, we set c = 1e + 5 in this problem. The Majorization-Minimization method for solving problem updates \mathbf{x} as

$$\mathbf{x^{(k+1)}} = \mathbf{soft}(\frac{1}{c}\mathbf{A^T}(\mathbf{y} - \mathbf{A}\mathbf{x^{(k)}}) + \mathbf{x^{(k)}}, \lambda/c),$$

where soft is called the soft-thresholding operator and is defined as follows: if $\mathbf{z} = \mathbf{soft}(\mathbf{x}, \sigma)$, then $z_i = sign(x_i) \max\{|x_i| - \sigma, 0\}$.

2) (8 points) Solve ℓ2 regularized LS using gradient descent method. The gradient descent method for solving problem updates x as

$$\mathbf{x} = \mathbf{x} - \gamma \cdot \nabla_{\mathbf{x}} f(\mathbf{x}),$$

where γ is the step size of the gradient decent methods. We suggest that you can set $\gamma = 1e - 5$.

- 3) (4 points) Compare two methods above.
 - (a) compare L0 norm (the number of non-zero elements) of x_{LS} computed by above two algorithms;
 - (b) Compare the loss $||\mathbf{A}\mathbf{x} \mathbf{y}||_2^2$ for results $\mathbf{x} = \mathbf{x_{LS}}$ of above two algorithms.

Remarks:

- The solution of the two methods should be printed in files named "sol1.txt" and "sol2.txt" and submitted in gradescope. The format should be same as the input file (210 rows plain text, each rows is a dimension of the final solution).
- Make sure that your codes are executable and are consistent with your solutions.

Solution.

- 1) Figure 1
- 2) Figure 2

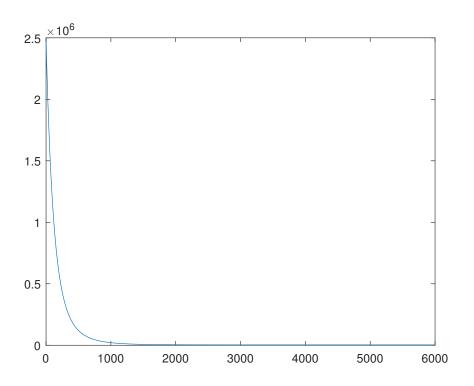

Figure 1: The L1 regularized LS

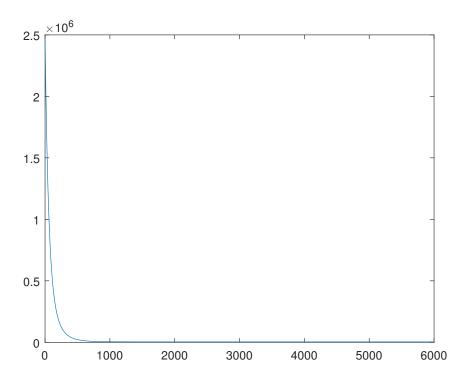

Figure 2: The L2 regularized LS

3) L0 norm of L1 regularized LS is 210.

L0 norm of L2 regularized LS is 210.

The loss $||\mathbf{A}\mathbf{x}-\mathbf{y}||_2^2$ of L1 regularized LS is 2.945643132698298e+03.

The loss $||\mathbf{A}\mathbf{x}-\mathbf{y}||_2^2$ of L2 regularized LS is 2.945528893965083e+03.

II. COMPUTATIONS OF SVD

Problem 2. In this problem you will see singular value stability and discover computation of SVD.

1) (4 points) Consider a 4×4 matrix

$$\mathbf{A} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ \frac{1}{6000} & 0 & 0 & 0 \end{bmatrix},$$

find its singular values and eigenvalues. In this sub-problem you can use eigenvalue decomposition ('eig') and singular value decomposition function ('svd') in Matlab or Python.

2) (8 points) Compute the SVD decomposition of a 3×2 matrix by Algorithm 1

$$\mathbf{B} = \begin{bmatrix} 3 & 2 \\ 1 & 4 \\ \frac{1}{2} & \frac{1}{2} \end{bmatrix}.$$

Are the results right? If not, can you get the correct answer through the results of Algorithm 1? The In this sub-problem you can use the eigenvalue decomposition ('eig') and QR decomposition function ('qr') in Matlab or Python.

3) (8 points) Consider an $m \times m$ upper triangular matrix with 0.1 on the main diagonal and 1 everywhere above the diagonal. Fine the smallest singular value through the singular value decomposition function ('svd') and algorithm 1. You are required to plot two curves on a log scale for $m = 1, \ldots, 30$ and show which one is the desired result.

Algorithm 1: SVD Decomposition by A^TA

Input: Thin matrix A

- 1 Form $\mathbf{A}^T \mathbf{A}$.
- 2 Compute the eigenvalue decomposition $\mathbf{A}^T \mathbf{A} = \mathbf{V}^T \mathbf{\Lambda} \mathbf{V}$.
- 3 Let Σ be an m×n diagonal matrix with diagonal entries being the nonnegative square root of diagonal entries of Λ .
- 4 Solve the system $U\Sigma = AV$ for orthogonal matrix U (e.g., via QR factorization).

Output: U, Σ, V .

Remarks

- 1) Singular values cannot be negative.
- 2) Please show your result and insert figures in your PDF.

Solution.

The singular values of A is [3, 2, 1, 1/6000].
 The eigenvalues of A is [-393/2210, 393/2210i, -393/2210i, 393/2210].

2) If we compute the SVD decomposition of B by Algorithm 1, the results is wrong.

We can get the correct answer by:

First: change the order of eigenvalues into descending.

Second: change the order of eigenvectors by the index of Frist-step.

Third: replace the V with the opposite of V.

3) Figure 3

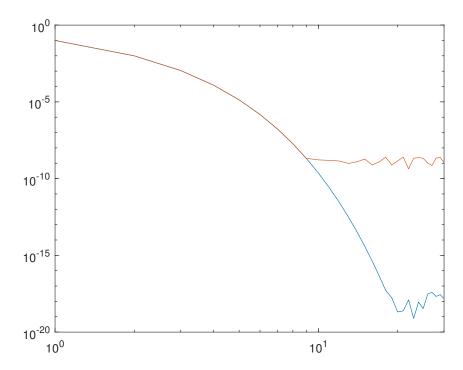

Figure 3: The smallest singular value

According to the relationship between the determinant of A and the diagonal elements of A, the singular value decomposition function's results are desired.

III. ITERATIVE METHODS.

Problem 3. In this problem, you will learn how to implement there iterative methods, Jacobi, Gauss-Seidel and SOR Methods to solve the linear equation $\mathbf{b} = \mathbf{A}\mathbf{x}$, and compare the convergence of these methods. "A1.txt", "A2.txt", "b1.txt", "b2.txt", "x1.txt", "x2.txt" is the data of the $\mathbf{b}, \mathbf{x}, \mathbf{A}$ with different size (10 and 1000 respectively).

Algorithm 2: Iterations method

Input: A starting point \mathbf{x}^0 , maximum iterations N, error bound eps

Output: Solution x of Ax = b

1 for
$$k = 0, 1, 2, \dots, N$$
 do

$$\mathbf{update} \ \mathbf{x}^k \ \text{to obtain} \ \mathbf{x}^{k+1} \ ;$$
 // Use one of the three iteration methods
$$\mathbf{if} \ \|\mathbf{x}^{k+1} - \mathbf{x}^k\|_2 < \mathrm{eps} \ \mathbf{then}$$

4 break;

5 end

6 end

Suppose
$$\mathbf{x} \in \mathbb{R}^n$$
, $\mathbf{A} = [a_{ij}] \in \mathbb{R}^{n \times n}$ and $\mathbf{b} = (b_i) \in \mathbb{R}^n$.

Each iteration method uses different updates:

For Jacobi Iteration,

$$x_i^{k+1} = (b_i - \sum_{i \neq j} a_{ij} x_j^k) / a_{ii}$$
 for $i = 1, \dots, n$,

For Gauss-Seidel Iteration,

$$x_i^{k+1} = (b_i - \sum_{j>i} a_{ij} x_j^{k+1} - \sum_{j$$

For SOR Iteration with relaxation factor ω ,

$$x_i^{k+1} = (1-\omega)x_i^k + \omega \left(b_i - \sum_{j>i} a_{ij}x_j^{k+1} - \sum_{j$$

Remarks:

- 1) (8 points) Implement the Jacobi Iteration and Gauss-Seidel Iteration methods.
- 2) (8 points) Implement the SOR Iteration method, tune the relaxation factor ω to achieve high convergence rate and plot the curve of number of iterations v.s. the value of ω .
- 3) (4 points) Plot the error $\|\mathbf{x}_{\text{true}} \mathbf{x}^k\|_2$ for k = 1, 2, ..., N, analyze the convergence rate and the final error of three methods.

Note: The value of the "eps" in Terminal condition should not be too large!

Solution.

The number of iteration of Jacobi Iteration with A1 and b1 is 13.
 The number of iteration of Gauss-Seidel Iteration with A1 and b1 is 7.

The number of iteration of Jacobi Iteration with A2 and b2 is 6.

The number of iteration of Gauss-Seidel Iteration with A2 and b2 is 5.

2) As shown in the Figure 4.

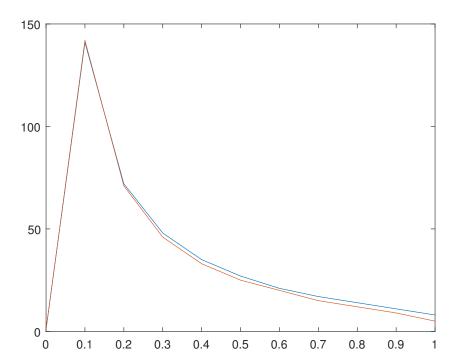

Figure 4: The number of iteration v.s. the avluse of $\boldsymbol{\omega}$

3) As shown in the Figure 5 and Figure 6.

We can see that the convergence rate of Gauss-Seidel is the fastest. And the final error of Gauss-Seidel is the smallest.

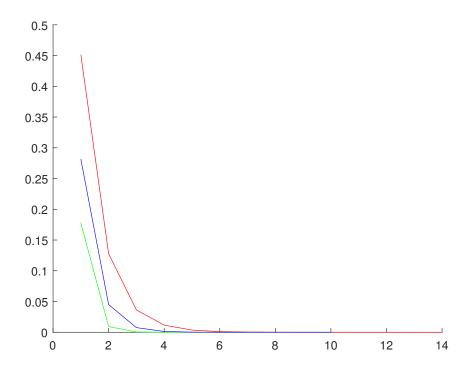

Figure 5: The loss of three method v.s. their numbers of iteration with A1 and b1

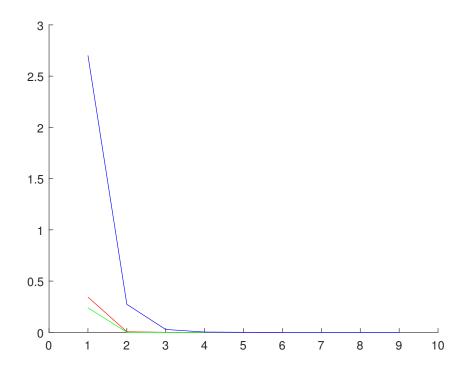

Figure 6: The loss of three method v.s. their numbers of iteration with A2 and b2

IV. APPLICATION OF SVD

Problem 4. In this problem you will see one of the application of SVD, what is doing face recognition on Yale B dataset. Here we will only use 4 individuals under 15 relatively brighter different illumination conditions.

Figure 7: Face images of one individual under 5 different illumination conditions in the extended YaleB dataset.

All images are frontal faces.

Face recongition is an area of computer vision in which low-dimensional linear models such as principal component analysis (PCA) and its variations have been popular tools for capturing the variability of face images. And it has been shown that PCA can be solved by SVD optimally. In the following questions you will see how Algorithm 3 can be used.

Algorithm 3: $[\mu, \mathbf{U}, \mathbf{Y}] = PCA_via_SVD(\mathbf{X}, d)$

1 Parameters:

- 2 X: $D \times N$ data matrix.
- 3 d: Number of principal components.

4 Returned values:

- 5 μ : Mean of the data.
- 6 U: Orthonormal basis for the subspace.
- 7 Y: Low-dimensional representation (or principal components).

8 Description:

- 9 Compute the SVD of the data matrix $\mathbf{X} \mu \mathbf{1}^T = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$.
- 10 Sort the singular values in descending order, choose the first d singular values and the corresponding d left singular vectors \mathbf{U}_d .
- 11 Find the d principal components $\mathbf{Y} = \mathbf{U}_d^T (\mathbf{X} \boldsymbol{\mu} \mathbf{1}^T)$

The principal bases U estimated by PCA are also known as the *eigenfaces* in the computer vision literature. The first eigenface is the left singular vector corresponding to the largest singular value, the second eigenface is the left singular vector corresponding to the second largest singular value and so on.

1) (4 points) Apply PCA in Algorithm 3 with d = 10 to individual 4¹. Plot the mean face μ , the first eigenface, the second eigenface, the third eigenface and the tenth eigenface. Describe what you have observed.

¹you can use the images or the mat file in data1 folder

- 2) (8 points) Apply PCA in Algorithm 3 with d = 10 to the Training Set.
 - a) Plot the mean face, the first eigenface, the second eigenface, the third eigenface and the tenth eigenface.
 - b) Plot the sorted singular values.
 - c) Project the Test Set onto the face subspace given by PCA, that is $\mathbf{Y}_{test} = \mathbf{U}_d^T (\mathbf{X}_{test} \boldsymbol{\mu} \mathbf{1}^T)$. Compute the projected faces, that is $\text{Proj}(\mathbf{X}_{test}) = \boldsymbol{\mu} \mathbf{1}^T + \mathbf{U}_d \mathbf{Y}_{test}$. Then choose one projected face for each individual and plot them. And show those projected faces for d=2 again.
- 3) (8 points) Classify these test faces using 1-nearest-neighbor, that is, label an image x as corresponding to individual i if its projected image y is closest to one of projected training image y_j of individual i^2 . Report the percentage of incorrectly classified face images for d = 2, ..., 8 and put them into the following table. Which value of d gives the best recognition performance?

Table I: Summary of errors

# eigenvectors	2	3	4	5	6	7	8
 error							

Remarks:

- 1) Data are provided in two forms: images and mat data. You only need to use one of them.
- 2) 10 images for each individuals in the training data, and 5 images for each individuals in the test data. All images are of the same size 48×42 .
- 3) In mat file all_data.mat, data_train and data_test are the matrices of training data and test data where each column is the column stack of an image³, Y_label_train and Y_label_test are ground truth labels.
- 4) 'Plot the mean face or eigenface' means you should reshape the vector to the size of image and show it.
- 5) Recommend to use truncated(thin) SVD for fast implementation.
- 6) Please insert your figures in your PDF.

Solution.

- As shown in the Figure8 and Figure9.
 We can observe that the first eigenface contains more infomation.
- 2) a) As shown in the Figure 10 and Figure 11.
 - b) As shown in the Figure 12.
 - c) As shown in the Figure 13 and Figure 14.

 $^{^2}$ we use ℓ_2 norm as the distance measurement: $\|y-y_j\|_2$

³the column stack of an image matrix $\mathbf{X} \in \mathbb{R}^{m \times n}$ is denoted by $x = [X_{11}, X_{21}, X_{31}, ..., X_{mn}]^T \in \mathbb{R}^{mn}$

Figure 8: The mean face

the first eigenface

the third eigenface

the second eigenface

the tenth eigenface

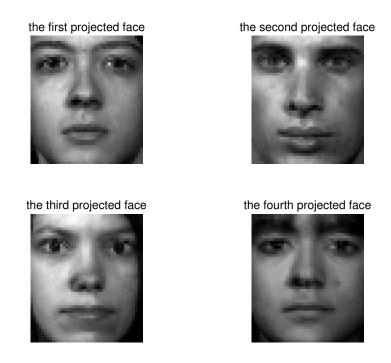

Figure 13: The projected faces with d=10

the first projected face

the third projected face

the second projected face

the fourth projected face

Figure 14: The projected faces with d=2

3) As shown in the Table2. And when d=8, we can get the best recognition performance.

Table II: Summary of errors

# eigenvectors	2	3	4	5	6	7	8
error	0.55	0.35	0.30	0.25	0.10	0	0

Problem 5. In this problem, we will learn how to use SVD to compress, or reduce the dimension of the data. The real data is with low rank internal, but often corrupted, or contaminated by noise, which leads to the full rank of the data matrix $\mathbf{A} \in \mathbb{R}^{D \times N}$. To reduce the storage consumption of the real data (note that D is extremely large in practical), we seek to find a low rank approximation to \mathbf{A} , that is, we want to solve the problem

$$\min_{\mathbf{X} \in \mathbb{R}^{D \times N}} \|\mathbf{X} - \mathbf{A}\|_F^2 \tag{3}$$

s.t.
$$\operatorname{rank}(\mathbf{X}) \le d$$
 (4)

where $\|\cdot\|_F$ is the Frobenius norm, d << D is unknown. By the Theorem of PCA via SVD, the above problem is equivalent to the following problem (suppose the eigenvalues of \mathbf{A} are given by $\sigma_1(\mathbf{A}) \geq \sigma_2(\mathbf{A}) \geq \cdots \geq \sigma_K(\mathbf{A}) \geq 0$ and $K = \min\{D, N\}$):

$$\min_{d=1,\dots,K} J(d) = \sum_{i=d+1}^{K} \sigma_i^2(\mathbf{A})$$
(5)

However, this is not a good criterion, since the optimal solution is given by $d^* = \operatorname{rank}(\mathbf{A})$ $(J(d^*) = 0)$.

The problem of determining the optimal dimension d is in fact a "model selection" problem, which is due to the fact that choice of d balances the complexity of the model and the storage of the data. There are many model selection criterion, we will learn two of them.

1) The first way is to bound the residual of approximation, that is, suppose $\hat{\mathbf{X}}$ is the best rank -d approximation of \mathbf{A} , given a threshold $\tau > 0$, we want to minimize the residual with respect to Frobinius-norm, that is

$$\min_{d=1,\dots,K} \|\mathbf{A} - \hat{\mathbf{X}}\|_F^2 \le \tau \tag{6}$$

the problem can be explicitly written as

$$d^* = \min_{d=1,\dots,K} \left\{ d \left| \sum_{i=d+1}^K \sigma_i^2(\mathbf{A}) \le \tau \right. \right\}$$
 (7)

2) Note that the first criterion (7) depends on specific problem (singular values of data matrix are not invariant with respect to linear transformations), it is hard to chose a reasonable threshold. To generalize our criterion, we consider the normalized version of (7), this new criterion, *a.k.a* variance explained ratio in machine learning, is given by

$$d^* = \min_{d=1,\dots,K} \left\{ d \left| \frac{\sum_{i=d+1}^K \sigma_i^2(\mathbf{A})}{\sum_{i=1}^K \sigma_i^2(\mathbf{A})} \le \tau \right. \right\}$$
(8)

Now, suppose the data matrix $\mathbf{A} \in \mathbb{R}^{D \times N}$ is the same as Problem 4 (data1/data1.mat). You are required to

- 1) (8 points) Plot the squared singular values of A along with the threshold $\tau = 150$, what is the solution to (7)?
- 2) (12 points, 6 points for plot, 6 points for table) Plot the figure of function

$$f(d) = \frac{\sum_{i=d+1}^{K} \sigma_i^2(\mathbf{A})}{\sum_{i=1}^{K} \sigma_i^2(\mathbf{A})}, \quad d = 1, \dots, K$$
(9)

and fill the following table from the figure with respect to (8):

au	0.1	0.05	0.02	0.005
Compression rate				

Table III: The compression rate with respect different threshold

where the compression rate is defined as

compression rate =
$$\frac{\#\{\text{entries in } \hat{\mathbf{X}}\}}{\#\{\text{entries in } \mathbf{A}\}} = \frac{d^*(D+N+1)}{DN}$$
 (10)

Remarks

- 1) Please insert your figures in your PDF.
- 2) You can just mark the solution of problem 1) on your figure (plot a vertical line with red color or mark the solution with marker).
- 3) Please draw a continuous curve for problem 2), see *stairs* function in Matlab, *plt.step* function in Python for more details.
- 4) For simplicity, we omit some proof details, you may refer to *Generalized Principal Component Analysis*, *Section 2.1* for more details.

Solution.

1) As shown in the Figure 15. And the solution to (7) is 2.

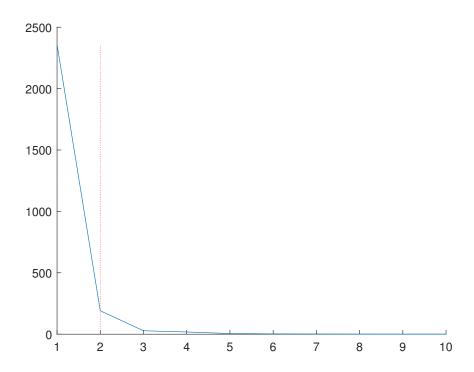

Figure 15: The squared singular values of A

2) As shown in the Figure 16 and Table 4.

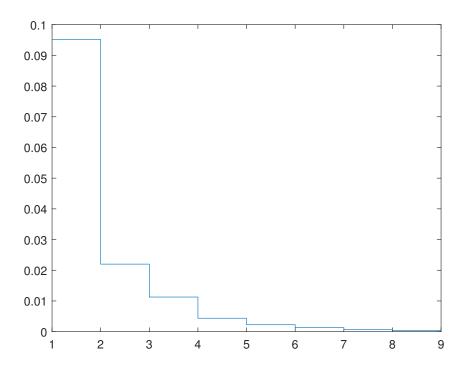

Figure 16: The figure of function f(d)

au	0.1	0.05	0.02	0.005	
Compression rate	0.1005	0.2011	0.3016	0.4022	

Table IV: The compression rate with respect different threshold
